6.1.1.3 Equivalent Isotropically Radiated Power

Test Requirement: EN 300 440-2 Clause 4.2.1.1

Test Method: EN 300 440-1 Clause 7.1.2

Ambient: Temp.: 25.0 °C Humid.: 57 % Press.: 1025 mbar

Test Status: 1) Keep the EUT in continuously transmitting with Modulation test single.
2) Test EUT in normal conditions, then repeat in extreme conditions.

Equipment Used: Refer to section 5 for details.

Test Procedure:

1. Using test software to set up the lowest channel, the middle channel, the highest channel.
2. The technique used to find the radiated power of the transmitter was the antenna substitution method. Substitution method was performed to determine the actual ERIP emission levels of the EUT.

The following test procedure as below:

- 1) The EUT was powered ON and placed on a 1.5m high table in the chamber. The antenna of the transmitter was extended to its maximum length.
- 2) The disturbance of the transmitter was maximized on the test receiver display by raising and lowering the receive antenna from 1m to 2m and by rotating through 360° the turntable. After the fundamental emission was maximized, a field strength measurement was made.
- 3) Steps 1) and 2) were performed with the EUT and the receive antenna in both vertical and horizontal polarization.
- 4) The transmitter was then removed and replaced with substitution antenna. The center of the antenna was approximately at the same location as the center of the transmitter.
- 5) A signal at the disturbance was fed to the substitution antenna by means of a non-radiating cable. With both the substitution and the receive antennas horizontally polarized, the receive antenna was raised and lowered to obtain a maximum reading at the test receiver. The level of the signal generator was adjusted until the measured field strength level in step 2) is obtained for this set of conditions.
- 6) The output power into the substitution antenna was then measured.
- 7) Steps 5) and 6) were repeated with both antennas polarized.
- 8) Pretest the EUT at different transmission time slot data and worst case data in the report.
- 9) Calculate power in dBm by the following formula:

$$\text{EIRP valuse (dBm)} = \text{Pg(dBm)} - \text{cable loss (dB)} + \text{antenna gain (dBi)}$$

where:

Pg is the generator output power into the substitution antenna.

6.1.3 Spurious Emissions

Test Requirement: EN 300 440-2 Clause 4.2.1.3

Test Method: EN 300 440-1 Clause 7.3.4

Ambient: Temp.: 26.0 °C Humid.: 56 % Press.: 1025 mbar

Test Status: 1) Keep the EUT in continuously transmitting with Modulation test single.
2) Keep the EUT in standby mode.
3) Test EUT in normal conditions.

Receiver Setup:

Frequency range	Measuring receiver bandwidth	Detector mode
25MHz-1000MHz	100kHz	QP
1GHz-25GHz	1MHz	Peak

Equipment Used: Refer to section 5 for details.

Test Setup:

Figure 1. 25MHz to 1GHz

Figure 2. Above 1GHz

Test Procedure:

- Using test software to set up the lowest channel (5730MHz), the middle channel (5795MHz), the highest channel (5845MHz).
- Scan from 25MHz to 25GHz, find the maximum radiation frequency to measure. No Standby Mode apply for the EUT.
- The technique used to find the Spurious Emissions of the transmitter was the antenna substitution method. Substitution method was performed to determine the actual ERP/EIRP emission levels of the EUT.

Below 1GHz test procedure as below:

- The EUT was powered ON and placed on a 1.5m high table in the chamber. The antenna of the transmitter was extended to its maximum length. If possible, without modulation and the measuring receiver shall be tuned to the frequency of the transmitter under test.
- The disturbance of the transmitter was maximized on the test receiver display by raising and lowering from 1m to 4m the receive antenna and by rotating through 360° the turntable. After the fundamental emission was maximized, a field strength measurement was made.
- Steps 1) and 2) were performed with the EUT and the receive antenna in both vertical and horizontal polarization.
- The transmitter was then removed and replaced with another antenna. The center of the antenna was approximately at the same location as the center of the transmitter.

- 5) A signal at the disturbance was fed to the substitution antenna by means of a non-radiating cable. With both the substitution and the receive antennas horizontally polarized, the receive antenna was raised and lowered to obtain a maximum reading at the test receiver. The level of the signal generator was adjusted until the measured field strength level in step 2) is obtained for this set of conditions.
- 6) The output power into the substitution antenna was then measured.
- 7) Steps 5) and 6) were repeated with both antennas polarized.
- 8) Calculate power in dBm by the following formula:

$$ERP(dBm) = Pg(dBm) - \text{cable loss (dB)} + \text{antenna gain (dBd)}$$

where:

Pg is the generator output power into the substitution antenna.

Above 1GHz test procedure as below:

Receiver Setup:

Frequency range	Measuring receiver bandwidth	Detector mode
25MHz-1000MHz	100kHz	QP
1GHz-25GHz	1MHz	Peak

Equipment Used: Refer to section 5 for details.

Test Setup:

Figure 1. 25MHz to 1GHz

Figure 2. Above 1GHz

Test Procedure:

1. Using test software to set up the lowest channel (5730MHz), the middle channel (5795MHz), the highest channel (5845MHz).
2. Scan from 25MHz to 25GHz, find the maximum radiation frequency to measure. No Standby Mode apply for the EUT.
3. The technique used to find the Spurious Emissions of the transmitter was the antenna substitution method. Substitution method was performed to determine the actual ERP/EIRP emission levels of the EUT.

Below 1GHz test procedure as below:

- 1) The EUT was powered ON and placed on a 1.5m high table in the chamber. The antenna of the transmitter was extended to its maximum length. Receiver mode and the measuring receiver shall be tuned to the frequency of the transmitter under test.
- 2) The disturbance of the transmitter was maximized on the test receiver display by raising and lowering from 1m to 4m the receive antenna and by rotating through 360° the turntable. After the fundamental emission was maximized, a field strength measurement was made.
- 3) Steps 1) and 2) were performed with the EUT and the receive antenna in both vertical and horizontal polarization.
- 4) The transmitter was then removed and replaced with another antenna. The center of the antenna was approximately at the same location as the center of the transmitter.
- 5) A signal at the disturbance was fed to the substitution antenna by means of a non-radiating cable. With both the substitution and the receive antennas

horizontally polarized, the receive antenna was raised and lowered to obtain a maximum reading at the test receiver. The level of the signal generator was adjusted until the measured field strength level in step 2) is obtained for this set of conditions.

- 6) The output power into the substitution antenna was then measured.
- 7) Steps 5) and 6)were repeated with both antennas polarized.
- 8) Calculate power in dBm by the following formula:

$$ERP(dBm) = Pg(dBm) - \text{cable loss (dB)} + \text{antenna gain (dBd)}$$

where:

Pg is the generator output power into the substitution antenna.

Above 1GHz test procedure as below:

- 1) Different between above is the test site, change from Semi- Anechoic Chamber to fully Anechoic Chamber and receiving antenna is moved from 1m to 2m.
- 2) Calculate power in dBm by the following formula:

$$EIRP(dBm) = Pg(dBm) - \text{cable loss (dB)} + \text{antenna gain (dBi)}$$

where:

Pg is the generator output power into the substitution antenna.
